Abstract
The closed orbit of the stored electrons in HLS storage ring often shifts due to some nonideal errors. In order to correct this shift, we developed an orbit correction system, which can be periodically or manually invoked to correct the global closed orbit. It can also be used to adjust the orbit position at some point using local bump. The system is based upon EPICS (Experimental Physics and Industrial Control system). It gets BPM data and sets corrector strength via Channel Access. SVD method is used to obtain the corrector strength or corrector factors in global or local orbit correction.

1 INTRODUCTION
HLS (Hefei Light Source) is a dedicated synchrotron light source. Electrons run at 800Mev in the storage ring[1]. The closed orbit of the stored electrons was often perturbed due to some nonideal errors. According to the experience of machine operation, the perturbed closed orbit, known as COD (Closed Orbit Distortion), has many bad effects. First, it excites the non-linear effect and leads to the decrease of the beam lifetime. Second, it changes the position of the light at the front-end of beam lines, which reduces the brightness of the light going into the beam line and affects the experiment at the responding experiment station. So, the COD should be corrected.

The COD correction system of HLS storage ring was constructed in Phase I project, which consisted three parts, corrector power supplies, control system, and BPM system. But the correction only can be performed off-line at a very low speed, because there are difficulties for the control system to read data from BPM system. During the Phase II project, all the three parts of the system are upgraded. The control system, which is based on EPICS, is not only can be used to control the correctors but can read beam position from BPM system.

2 SYSTEM DESCRIPTION
The new COD correction system of HLS storage ring can be described like fig 1. There are 22 BPMs along the ring. The BPMs are monitored by a labView based software, which works in client/server mode[3]. Acting as clients, a number of EPICS records, which rest in an IOC, read the BPM data from the server. The correctors are controlled by another IOC. There are 32 correctors along the storage ring, 16 of them are used for horizontal correction and others for vertical. The COD correction software runs on a SUN workstation, which gets BPM data and sets corrector strength via Channel Access. The software can be periodically or manually invoked to correct the global closed orbit. In other circumstances, it needs to change the orbit locally and not affecting the orbit at other site, for example, the measurement of BPM-to-quadruple misalignment. This system can also be used to adjust the orbit position at some point using local bump. SVD method is used to obtain the corrector strength or corrector factors in global or local orbit correction. The response matrix is measured by varying the strength of the horizontal and vertical corrector magnets or constructed from calculated optics.

3 RESPONSE MATRIX
The response matrix between these BPMs and 16 horizontal and 16 vertical correctors can be constructed from calculated optics or measured on the machine. Both kinds of matrices are in the correction.

2.1 Theoretical response matrix
A corrector at point $s_i$ deflect the beam by a angle $\theta_i$, then at point $s_j$, the beam position would be[4]:

$$u_0(s_j) = \frac{\sqrt{\beta_j}}{2 \sin (\pi v)} \theta_i \sqrt{\beta_i} \cos v(\varphi_j - \varphi_i - \pi) \tag{1}$$

Writing it in matrix format, we get:

$$U = M \Theta \tag{2}$$

Where, $U$ is the beam orbit position, $\Theta$ is the strength of correctors, $M$ is called response matrix between BPM and correctors, whose elements are:
$M_{ij} = \frac{\beta_i \beta_j}{2 \sin(\pi \nu)} \cos(\phi_i - \phi_j + \pi)$ \hspace{1cm} (3)

### 2.2 Measured Response Matrix

The response matrix can also be measured by changing the strength of each corrector by a small amount and then measuring the resulting beam motion at all BPMs. In our case, the strength of each corrector is changed in 5 steps. For each step, the power supply of this corrector is changed 1.0 ampere. The measured matrix is used in horizontal correction and got good result.

### 2.3 SVD method

Solving equation (2), we get,

\[ \Theta = M^{-1}U \] \hspace{1cm} (4)

In our case, M is a 22 by 16 matrix. Its inverse matrix can’t be directly solved. According the SVD method, M can written as the product, \( M = U^T W V \), of three matrix[5]. Where \( W \) is an 22 by 16 diagonal matrix with non-negative diagonal elements called the singular values, \( U \) is 22 by 22 matrix with \( UU^T = 1 \), and \( V \) is an 16 by 16 matrix with \( VV^T = 1 \). Then the pseudo-inverse matrix of M can be written as:

\[ M^{-1} = V^T W^{-1} U \] \hspace{1cm} (5)

Where \( M^{-1} \) is a 16 by 22 matrix.

### 3 LOCAL CORRECTION WITH BUMP

There are some conditions that need steering the beam locally, for example, in the measurement of BPM-to-quadruple misalignment. Local correction is based on three-correction local bump theory. The local bump is determined by the ratio of the strength of the three correctors, which is

\[ \frac{\sin \phi_{23}}{\sqrt{\beta_1}} : \frac{\sin \phi_{13}}{\sqrt{\beta_2}} : \frac{\sin \phi_{12}}{\sqrt{\beta_3}} \] \hspace{1cm} [6].

But on HLS storage ring, we can’t get good bump with this ratio especially in horizontal plan, because there are some not known non-ideal errors. So we use the response matrix to construct the bump. Let us suppose that we use three correctors \( c_1, c_2 \) and \( c_3 \) to form a bump at the point of BPMs \( b_1, b_2 \). Now we must construct two matrices. The first, \( M_1 \), is a 22 by 1 matrix, which corresponding to the column for corrector \( c_1 \) in the response matrix but haven’t the row corresponding to \( b_1 \) and \( b_2 \). Another, \( M_2 \), is a 22 by 2 matrix, which corresponding to the columns for corrector \( c_2 \) and \( c_3 \) in the response matrix but haven’t the row corresponding to \( b_1 \) and \( b_2 \). Let us further suppose that the strength of \( c_1 \) is 1, so we can get the strength of \( c_2 \) and \( c_3 \) with the following equation,

\[ \begin{bmatrix} c_2 \\ c_3 \end{bmatrix} = -M_2^{-1}M_1 I \] \hspace{1cm} (6)

Where I is unit matrix. Equation (6) means that \( c_1 \) with strength 1 change the closed orbit to \( M_1 I \) and corrected with \( c_2 \) and \( c_3 \) outside of the bump.

With this method, we get good result in both planes. Figure 2 and figure 3 shows the local bump in horizontal and vertical plane respectively.

### 4 GLOBAL CORRECTION

We use sddscontrollaw to do the global orbit correction, which is a SDDS-compliant EPICS tool developed at APS and based upon the integral control equation described as[7]:

\[ U_n = U_{n-1} - KX_n \] \hspace{1cm} (7)

The quantity \( X_n \) is the vector of measured BPM data at step \( n \). \( U_n \) is the corrector strength at step \( n \). \( K \) is the inverse response matrix plus a gain number. We get a good result in vertical plane. Figure 3 shows the closed orbit before correction. Figure 4 shows the closed orbit after correction. The standard deviation is reduced from 1.366 to 0.034. The maximum orbit deviation is reduced from 3.419mm to 0.079mm.
5 CONCLUSION

This system works fine in both local orbit correction and global orbit correction. The local correction with three-corrector bump is successfully used in the measurement of BPM-to-quadruple misalignment and get good result. The global correction in vertical plane also shows good result. Because the corrector power supply upgrade is not completed, we can’t do the global correction in horizontal plane. This system should work fine in horizontal plane after the power supply upgrade finished.

6 ACKNOWLEDGEMENT

The authors would like to thank Dr. M. Borland and all other members of APS operation analysis group, who provide us so many good tools to do the work.
